MIT LINCOLN LABORATORY

Interpretable Neural Networks for Visual Reasoning

Researchers at Lincoln Laboratory have developed a neural network model called Transparency by Design that not only answers complex questions about the contents of images but also makes its reasoning understandable to humans. The network explicitly models each step in its process for deriving the answer and "shows its thinking" as it solves the query.

KEY FEATURES

- Modular neural network breaks questions down into their logical components
- Intermediate model outputs allow human operators to understand network operation
- State-of-the-art performance on challenging academic datasets

Because the neural network outputs the regions of the image that the model finds important at each step, it allows a user to build intuition about how the model works and to double-check its performance. Transparency by Design's process leads to diagnostic insights; when the model returns an incorrect answer, the visibility of its "thought process" allows the user to understand what led to the faulty answer. These capabilities that provide interpretability also provide users a level confidence in the model's accuracy.

Transparency by Design's modularity allows analysts to reuse atomic operations (e.g., find red objects, find cubes, compare colors, etc.) and naturally enables the breakdown of questions into their constituent parts and the composition of operations for expressivity.

Transparency by Design achieved state-of-the-art performance on an academic dataset, surpassing similar modular approaches. It also achieves state-of-the-art results on a challenging generalization task. What color is the sphere to the left of the large metal sphere and right of the purple cube? Filter size large Filter color Filter material purple metal Filter shape Filter shape cube sphere Relate Relate right left Intersect Filter shape sphere Query Answer = green color
